

**This script is a simple command-line program that allows the user to input a string and then repeatedly mutate the string by changing a single character at a specified position in the string.**

**The program uses the Colorama library to add color to the console output. It defines a function called "mutate\_string" which takes three arguments: the original string, the position of the character to be changed, and the new character. The function returns the mutated string.**

**The program uses a loop to handle multiple input strings. For each input string, it uses another loop to handle multiple position and character inputs. It prompts the user to enter a position and a character, and it calls the "mutate\_string" function with the input values to get the mutated string. It then prints the mutated string to the console.**

**The program also checks for various errors, such as invalid input values and positions out of range, and provides appropriate error messages to the user.**

**The output of the program will depend on the input values provided by the user. For each mutation operation, the program will print the original string and the mutated string. If an error occurs, such as an invalid input value or a position out of range, the program will print an error message. If the user enters 'exit' at any prompt, the program will exit the current loop or the entire program, depending on the context. At the end of each input string, the program will ask the user if they want to enter another string. If the user chooses to exit, the program will terminate.**
